

General Description

The P24C64G is I²C-compatible Serial EEPROM (Electrically Erasable Programmable Memory) device. It contains a memory array of 64 Kbits (8 Kbytes), which is organized in 32 bytes per page.

Features

- Single Supply Voltage and High Speed Mode
 - ◇ Minimum operating voltage down to 1.65V
 - ◇ 400kHz/1MHz clock from 1.65 V to 3.6 V
 - ◇ 3.4MHz clock from 1.65V to 3.6V
- Low power CMOS technology
 - ◇ Read current 0.15mA (400kHz, typical)
- Schmitt Trigger, Filtered Inputs for Noise Suppression
- Transparent ECC on each group of four bytes which can correct 1 bit error
- Additional write lockable page (Identification page)
- Additional 128 bits Serial Number (Unique ID)
- Additional Write Lockable Page
- 32 bytes Page Write Modes, Partial Page Writes Allowed
- Write protect of the whole memory array
- Self-timed Write Cycle (5ms maximum)
- High Reliability
 - ◇ Endurance: 1 Million Write Cycles
 - ◇ Data Retention: 100 Years
 - ◇ HBM: 4 kV
 - ◇ Latch up Capability: +/- 200mA(25C)
- Package:
 - ◇ PDIP8,SOP8,MSOP8,TSSOP8,DFN8 and UDFN8

1. Pin Configuration

1.1 Pin Configuration

Figure 1-1 Pin Configuration

1.2 Pin Definition

Table 1-1 Pin Definition

Pin	Name	Type	Description
1	E0	Input	Slave Address Setting
2	E1	Input	Slave Address Setting
3	E2	Input	Slave Address Setting
4	Vss	Ground	Ground
5	SDA	I/O	Serial Data Input and Serial Data Output
6	SCL	Input	Serial Clock Input
7	WCB	Input	Write Control, Low Enable Write
8	Vcc	Power	Power

1.3 Pin Descriptions

Serial Clock (SCL): The SCL input is used to positive-edge clock data in and negative-edge clock data out of each device.

Serial Data (SDA): The SDA pin is bidirectional for serial data transfer. This pin is open drain driven and may be wire-OR'ed with any number of other open-drain or open-collector devices.

Device Addresses (E2, E1, E0): The E2, E1, and E0 pins are device address inputs. Typically, the E2, E1, and E0 pins are for hardware addressing and a total of 8 devices can be connected on a single bus system. If these pins are left floating, the E2, E1, and E0 pins will be internally pulled down to Vss .

Write Control (WCB): The Write Control input, when WCB is connected directly to Vcc, all write operations to the memory are inhibited. When connected to Vss , allows normal write operations. If the pin is left floating,

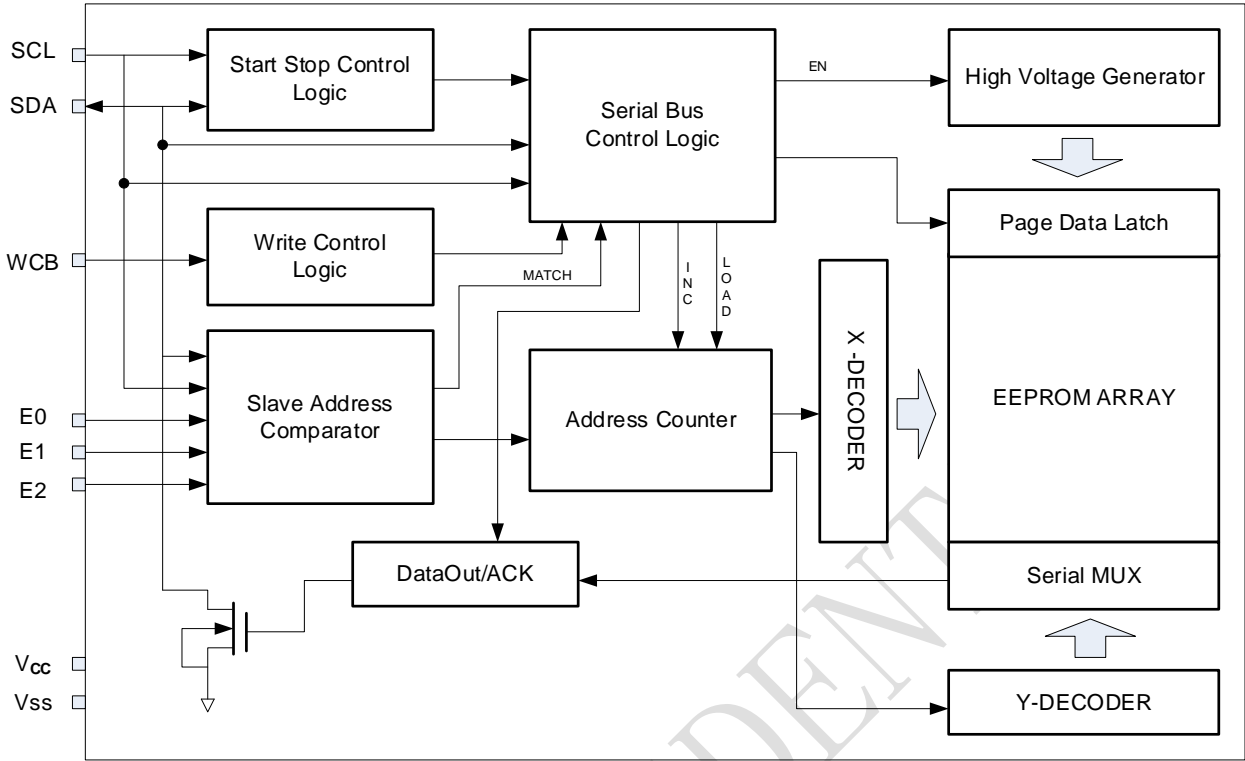

the WCB pin will be internally pulled down to Vss .

Supply Voltage (V_{cc}): V_{cc} is the supply voltage.

Ground (V_{ss}): V_{ss} is the reference for the V_{cc} supply voltage.

3. Electrical Characteristics

Table 3-1 Absolute Maximum Ratings ^[1]

Symbol	Parameter	Min.	Max.	Units
T _{STG}	Storage Temperature	-65	150	°C
T _A	Ambient operating temperature	-40	85	°C
V _{CC}	Supply Voltage	-0.5	4.0	V
V _{IO}	Input or output range	-0.5	4.0	V
I _{OL}	DC output current (SDA=0)	-	5	mA

Note: [1] Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operational listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

Table 3-2 Pin Capacitance ^[1]

Symbol	Parameter	Max.	Units	Test Condition
C _{I/O}	Input/output Capacitance (SDA)	8	pF	V _{I/O} = V _{SS}
C _{IN}	Input Capacitance (SCL)	6	pF	V _{IN} = V _{SS}

Note: [1] Test Conditions: T_A= 25°C, f_{SCL} = 1MHz, V_{CC} =3.6V.

Table 3-3 DC Characteristics(Unless otherwise specified, V_{CC} = 1.65 V to 3.6V, T_A= -40°C to +85°C)

Symbol	Parameter	Min.	Typ.	Max.	Unit	Test Condition
V _{CC}	Supply Voltage	1.65	-	3.6	V	T _A = -40 °C to 85 °C
I _{sb}	Standby Current (Standby mode)	-	0.1	3.0	uA	V _{CC} = 1.8V, V _{in} = V _{SS} or V _{CC} Device is not selected
I _{CC1}	Supply Current (Read)	-	0.15	0.5	mA	V _{CC} = 1.8V, f _{SCL} = 400KHz
		-	-	0.5	mA	V _{CC} = 3.6V, f _{SCL} = 400KHz
		-	-	1.0	mA	V _{CC} = 3.6V, f _{SCL} = 1MHz
		-	-	3.0	mA	V _{CC} = 3.6V, f _{SCL} = 3.4MHz
I _{CC2}	Supply Current (Write)	-	1.0	2.0	mA	During t _w , 1.65V < V _{CC} < 3.6V
I _{LI}	Input Leakage Current	-2	-	+2.0	μA	V _{IN} = V _{CC} or V _{SS} , device in standby mode
I _{LO}	Output Leakage Current	-2	-	+2.0	μA	SDA in Hi-Z, external voltage applied on SDA: V _{SS} or V _{CC}
V _{IL}	Input Low Voltage	-0.45	-	0.3 V _{CC}	V	SCL, SDA
V _{IH}	Input High Voltage	0.7V _{CC}	-	V _{CC} +0.5	V	SCL, SDA

Figure 3-1 Bus Timing

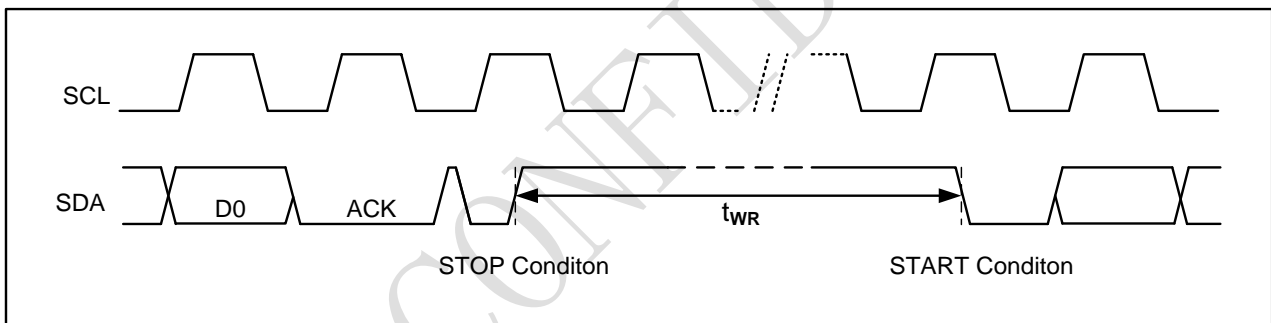

Figure 3-2 Write Cycle Timing

Note: [1] The write cycle time t_{WR} is the time from a valid stop condition of a write sequence to the end of the internal write cycle.

Device Power-Up

The EEPROM has a built-in power-on-reset circuit that initializes itself at the same time during power-on. Unsuccessful initialization may cause a malfunction. To operate the power-on-reset circuit normally, the following conditions must be satisfied to raise the power supply voltage.

When initialization is successfully completed by the power-on-reset circuit, the EEPROM enters the standby status. t_{VSL} is the time required to initialize the EEPROM. No instructions are accepted during this time.

Figure 3-3 Power up Timing

Power Up/Down and Voltage Drop

For Power-down to Power-up operation, the VCC of EEPROM device must below VPWD for at least tPWD timing. Please check the table below for more detail.

Figure 3-4 Power down-up Timing

Symbol	Parameter	min	max	unit
VPWD	VCC voltage needed to below VPWD for ensuring initialization will occur		0.7	V
tPWD	The minimum duration for ensuring initialization will occur	300		us
tVSL	VCC(min.) to device operation	100		us
tVR	VCC Rise Time	1	500000	us/V

4. Device Operation

4.1 Data Input

The SDA pin is normally pulled high with an external device. Data on the SDA pin may change only during SCL low time periods (see to Figure 4-1). Data changes during SCL high periods will indicate a start or stop condition as defined in Figure 4-2.

Figure 4-1 Data Validity

4.2 Start Condition

A high-to-low transition of SDA with SCL high is a start condition which must precede any other command (see to Figure 4-2).

4.3 Stop Condition

A low-to-high transition of SDA with SCL high is a stop condition. After a read sequence, the stop command will place the P24C64G in a standby mode (see Figure 4-2).

Figure 4-2 Start and Stop Definition

4.4 Acknowledge (ACK)

All addresses and data words are serially transmitted to and from the P24C64G in 8-bit words. The P24C64G

sends a “0” to acknowledge that it has received each word. This happens during the ninth clock cycle.

Figure 4-3 Output Acknowledge

4.5 Power Up Sequence

During a power-up sequence, the V_{CC} supplied to P24C64G should monotonically rise from V_{SS} to the minimum V_{CC} level with a slew rate no greater than 1V/us.

To prevent inadvertent write operations or other spurious events from happening during a power-up sequence, the P24C64G includes a power-on-reset circuit. Upon power-up, the device will not respond to any commands until the V_{CC} level crosses the internal voltage threshold and waiting 100 μ s that brings the device out of reset and into standby mode.

4.6 Standby Mode

The P24C64G features a low-power standby mode which is enabled: (a) after a fresh power up, (b) after receiving a STOP bit in read mode, and (c) after completing a self-time internal programming operation

4.7 Soft Reset

After an interruption in protocol, power loss or system reset, any two-wire part can be reset by following these steps: (a) Create a start condition, (b) Clock nine cycles, and (c) create another start bit followed by stop bit condition, as shown below. The device is ready for the next communication after the above steps have been completed.

Figure 4-4 Soft Reset

4.8 Device Addressing

The P24C64G requires an 8-bit device address word following a start condition to enable the chip for a read or write operation (see Figure4-5). The device address word consists of a mandatory one-zero sequence for the first four most-significant bits, as shown.

Figure 4-5 Device Address

The three E2, E1, and E0 device address bits allow as many as eight devices on the same bus. These bits must compare to their corresponding hardwired input pins.

The E2, E1, and E0 pins use an internal proprietary circuit that biases them to a logic low condition if the pins are floating.

The eighth bit of the device address is the read/write operation select bit. A read operation is initiated if this bit is high and a write operation is initiated if this bit is low. Upon a compare of the device address, the Chip will output a zero. If a compare is not made, the device will return to a standby state.

Table 4-1 Device Address

Chip	Access area	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
P24C64G	Normal Area	1	0	1	0	E2	E1	E0	R/W
	ID Page	1	0	1	1	E2	E1	E0	R/W

	Lock Bit	X	X	X	X	X	X	X	X
	Serial Number	X	X	X	X	A3	A2	A1	A0

4.9 Data Security

P24C64G has a hardware data protection scheme that allows the user to write protect the whole memory when the WCB pin is Vcc.

4.10 ECC (Error Correction Code) and Write cycling

The Error Correction Code (ECC) is an internal logic function which is transparent for the I2C communication protocol.

The ECC logic is implemented on each group of four EEPROM bytes^[1]. Inside a group, if a single bit out of the four bytes happens to be erroneous during a Read operation, the ECC detects this bit and replaces it with the correct value. The read reliability is therefore much improved.

Even if the ECC function is performed on groups of four bytes, a single byte can be written/cycled independently. In this case, the ECC function also writes/cycles the three other bytes located in the same group^[1]. As a consequence, the maximum cycling budget is defined at group level and the cycling can be distributed over the 4 bytes of the group: the sum of the cycles seen by byte0, byte1, byte2 and byte3 of the same group must remain below the maximum value.

Note: [1] A group of four bytes is located at addresses $[4*N, 4*N+1, 4*N+2, 4*N+3]$, where N is an integer

4.11 High Speed Mode (HS-mode)

The P24C64G supports 3.4MHz high speed mode. A master code (00001XXXb) must be issued to place the device into high speed mode. Communication between master and slave will then be enabled for speeds up to 3.4MHz. A STOP condition will exit HS-mode. Single-byte and multiple-byte read and write are supported.

Figure 4-6 High Speed Communication

PUYA CONF

5. Instructions

5.1 Write Operations

5.1.1 Byte Write

A write operation requires two 8-bit data word address (A12~A0) following the device address word and acknowledgment. Upon receipt of this address, the P24C64G will again respond with a “0” and then clock in the first 8-bit data word. Following receipt of the 8-bit data word, the P24C64G will output a “0” and the addressing device, such as a microcontroller, must terminate the write sequence with a stop condition. And then the P24C64G enters an internally timed write cycle, all inputs are disabled during this write cycle and the P24C64G will not respond until the write is complete (see Figure 5-1).

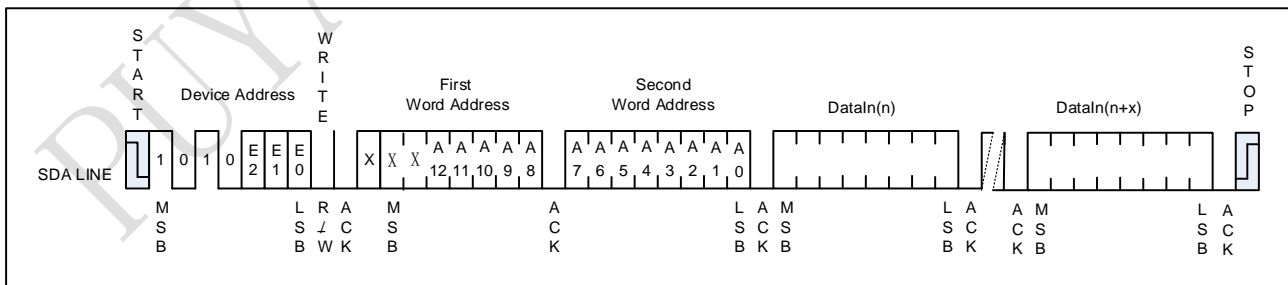

Figure 5-1 Byte Write

5.1.2 Page Write

A page write is initiated the same as a byte write, but the master does not send a stop condition after the first data word is clocked in. Instead, after the P24C64G acknowledges receipt of the first data word, the master can transmit more data words. The P24C64G will respond with a “0” after each data word received. The microcontroller must terminate the page write sequence with a stop condition.

Figure 5-2 Page Write

The lower five bits of the data word address are internally incremented following the receipt of each data word. The higher data word address bits are not incremented, retaining the memory page row location. When the word address, internally generated, reaches the page boundary, the following byte is placed at the beginning of the same page. If more than 32 data words are transmitted to the P24C64G, the data word address will roll over, and previous data will be overwritten. The address roll over during write is from the last byte of the current page to the first byte of the same page.

5.1.3 Acknowledge Polling

Once the internally timed write cycle has started and the P24C64G inputs are disabled, acknowledge polling can be initiated. This involves sending a start condition followed by the device address word. The read/write bit is representative of the operation desired. Only if the internal write cycle has completed will the P24C64G respond with a “0”, allowing the read or write sequence to continue.

5.1.4 Write Identification Page

The Identification Page (32 bytes) is an additional page which can be written and later permanently locked in Read-only mode. It is written by the Write Identification Page instruction. This instruction uses the same protocol and format as Page Write, except for the following differences:

- Device type identifier = 1011b
- MSB address A11~A10 must be “0” while other bits in A12~A5 are don’t care.
- LSB address bits A4~A0 define the byte address inside the Identification page. If the Identification page is locked, the data bytes transferred during the Write Identification Page instruction are not acknowledged (NoACK).

5.1.5 Lock Identification Page

The Lock Identification Page instruction (Lock ID) permanently locks the Identification page in Read-only mode. The Lock ID Page instruction is similar to Byte Write with the following specific conditions:

- Device type identifier = 1011b
- Address bit A10 must be ‘1’; all other address bits are don’t care
- The data byte must be equal to the binary value xxxx xx1x, where x is don’t care

5.2 Read Operations

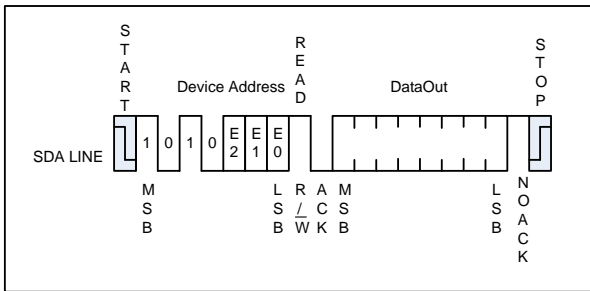

Read operations are initiated the same way as write operations with the exception that the read/write select bit in the device address word is set to “1”. There are three read operations: Current Address Read; Random Address Read and Sequential Read.

5.2.1 Current Address Read

The internal data word address counter maintains the last address accessed during the last read or write operation, incremented by one. This address stays valid between operations as long as the chip power is maintained. The address roll-over during read is from the last byte of the last memory page to the first byte of the first page.

Once the device address with the read/write select bit set to “1” is clocked in and acknowledged by the P24C64G, the current address data word is serially clocked out. The microcontroller does not respond with an input “0” but does generate a following stop condition (see Figure 5-3).

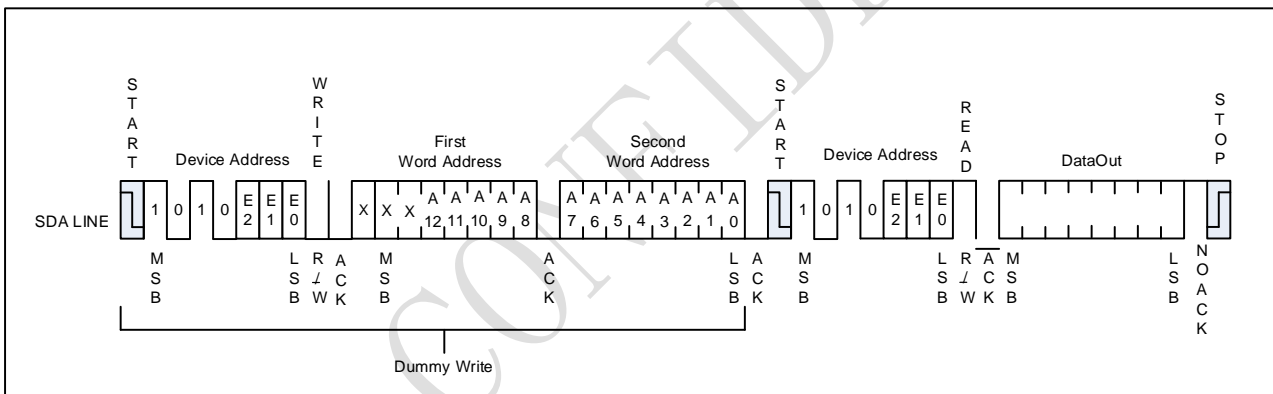

Figure 5-3 Current Address Read

5.2.2 Random Read

A Random Read requires a “dummy” byte write sequence to load in the word address. Once the device address word and word address are clocked in and acknowledged by the P24C64G, the microcontroller must generate another start condition. The microcontroller now initiates a Current Address Read by sending a device address with the read/write select bit high. The P24C64G acknowledges the device address and serially clocks out the data. The microcontroller responds with a “1” and generates stop condition (see Figure 5-4).

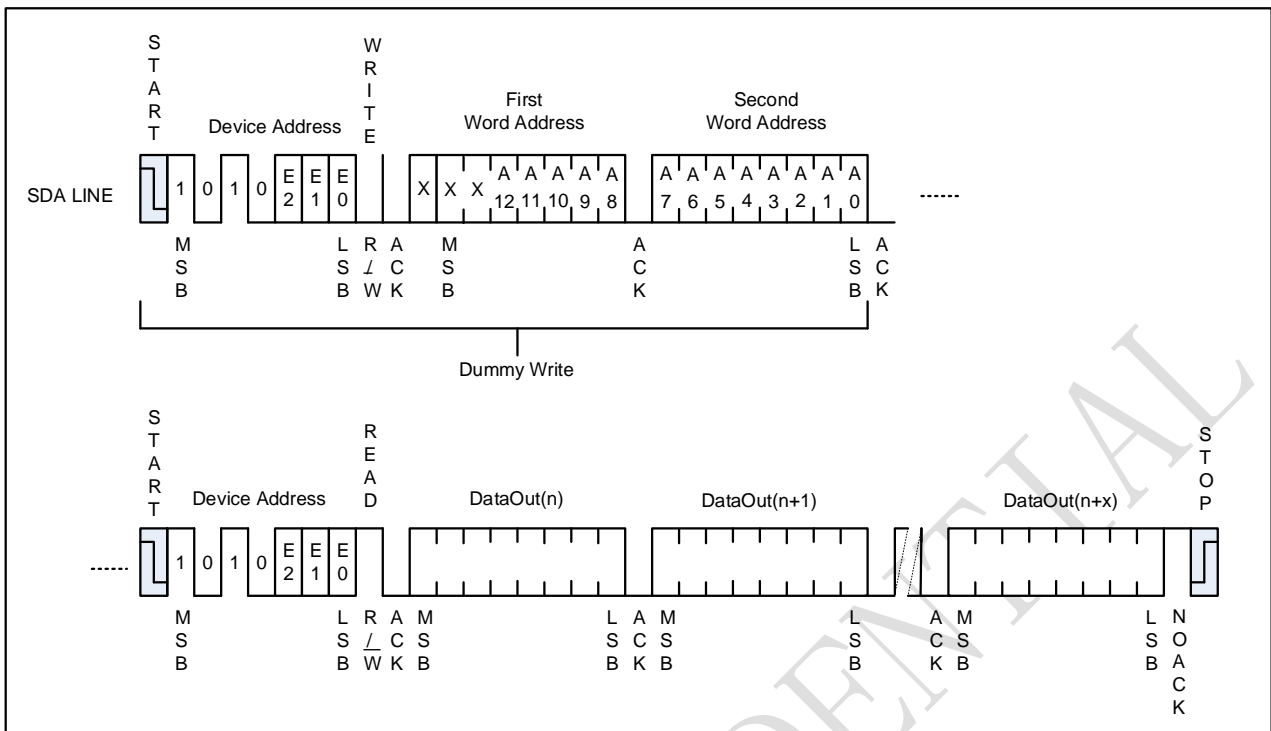

Figure 5-4 Random Read

5.2.3 Sequential Read

Sequential Reads are initiated by either a Current Address Read or a Random Address Read. After the microcontroller receives a data byte, it responds with acknowledge. As long as the P24C64G receives acknowledge, it will continue to increment the word address and serially clock out sequential data. When the memory address limit is reached, the word address will roll-over and the Sequential Read will continue. The Sequential Read operation is terminated when the microcontroller responds with a “1” and generates a stop condition (see Figure 5-5).

Figure 5-5 Sequential Read

5.2.4 Read Identification Page

The Identification Page (32 bytes) is an additional page which can be written and later permanently locked in Read-only mode. The Identification Page can be read by Read Identification Page instruction which uses the same protocol and format as the Read Command with device type identifier defined as 1011b. The MSB address bits A12~A5 are don't care, the LSB address bits A4~A0 define the byte address inside the Identification Page. The number of bytes to read in the ID page must not exceed the page boundary (e.g. When reading the Identification Page from location 10d, the number of bytes should be less than or equal to 22, as the ID page boundary is 32 bytes).

5.2.5 Read Lock Status

The locked/unlocked status of the Identification page can be checked by transmitting a specific truncated command [Identification Page Write instruction + one data byte] to the device. The device returns an acknowledge bit if the Identification page is unlocked, otherwise a NO-ACK bit if the Identification page is locked.

Figure 5-6 Lock Status Read (When Identification page locked, return NO-ACK after the data-in)

5.2.6 Read Serial Number

Reading the serial number is similar to the sequential read sequence but requires use of the device address seen in Table 4-1, and the use of a specific word address. The entire 128 bits value must be read from the starting address of the serial number block to guarantee a unique number.

Since the address pointer of the device is shared between the regular EEPROM array and the serial number block, a dummy write sequence, as part of a Random Read or Sequential Read protocol, should be performed to ensure the address pointer is set to zero. Reading the serial number from a location other than the first address of the block will not result in a unique serial number.

Additionally, the word address contains a '10' sequence in bit A11 and A10 of the word address, regardless of the intended address as depicted in Table 4-2. If a word address other than '10' is used, then the device will output unintended data.

When the end of the 128 bits serial number is reached (16 bytes of data), continued reading of the extended memory region will result in an additional 16 bytes of 00h data. Upon reaching the end of the 16 bytes extended memory region, the data word address will roll-over back to the beginning of the 128 bits serial number. The Serial Number Read operation is terminated when the master does not respond with a zero (ACK) and instead issues a STOP bit (Refer to Figure 5-7)

Figure 5-7 Serial Number Read
